

Linear in the parameters regression

Carl Edward Rasmussen

June 23rd, 2016

How do we fit this dataset?

- Dataset $\mathcal{D} = \{x_i, y_i\}_{i=1}^N$ of N pairs of inputs x_i and targets y_i . This data can for example be measurements in an experiment.
- Goal: predict target y_* associated to any arbitrary input x_* . This is known as a **regression** task in machine learning.
- Note: Here the inputs are scalars, we have a single **input feature**. Inputs to regression tasks are often vectors of multiple input features.

Model of the data

- In order to predict at a new x_* we need to postulate a model of the data. We will estimate y_* with $f(x_*)$.
- But what is $f(x)$? Example: a polynomial

$$f_w(x) = w_0 + w_1 x + w_2 x^2 + w_3 x^3 + \dots + w_M x^M$$

The w_j are the weights of the polynomial, the **parameters** of the model.

Model of the data. Example: polynomials of degree M

Model structure and model parameters

- Should we choose a polynomial?
- What degree should we choose for the polynomial?
- For a given degree, how do we choose the weights?
- For now, let find the single “best” polynomial: degree and weights.

model structure

model structure

model parameters

Fitting model parameters: the least squares approach

- Idea: measure the quality of the fit to the training data.
- For each training point, measure the squared error $e_i^2 = (y_i - f(x_i))^2$.
- Find the parameters that minimise the sum of squared errors:

$$E(\mathbf{w}) = \sum_{i=1}^N e_i^2$$

$f_{\mathbf{w}}(\mathbf{x})$ is a function of the parameter vector $\mathbf{w} = [w_0, w_1, \dots, w_M]^T$.

Least squares in detail. (1) Notation

Some notation: training targets \mathbf{y} , predictions \mathbf{f} and errors \mathbf{e} .

- $\mathbf{y} = [y_1, \dots, y_N]^\top$ is a vector that stacks the N training targets.
- $\mathbf{f} = [f_{\mathbf{w}}(x_1), \dots, f_{\mathbf{w}}(x_N)]^\top$ stacks $f_{\mathbf{w}}(x)$ evaluated at the N training inputs.
- $\mathbf{e} = \mathbf{y} - \mathbf{f}$ is the vector of training prediction errors.

The sum of squared errors is therefore given by

$$E(\mathbf{w}) = \|\mathbf{e}\|^2 = \mathbf{e}^\top \mathbf{e} = (\mathbf{y} - \mathbf{f})^\top (\mathbf{y} - \mathbf{f})$$

More notation: weights \mathbf{w} , basis functions $\phi_j(x)$ and matrix Φ .

- $\mathbf{w} = [w_0, w_1, \dots, w_M]^\top$ stacks the $M + 1$ model weights.
- $\phi_j(x) = x^j$ is a **basis function** of our **linear in the parameters** model.

$$f_{\mathbf{w}}(x) = w_0 \mathbf{1} + w_1 x + w_2 x^2 + \dots + w_M x^M = \sum_{j=0}^M w_j \phi_j(x)$$

- $\Phi_{ij} = \phi_j(x_i)$ allows us to write $\mathbf{f} = \Phi \mathbf{w}$.

Least squares in detail. (2) Solution

A Gradient View. The sum of squared errors is a convex function of \mathbf{w} :

$$E(\mathbf{w}) = (\mathbf{y} - \mathbf{f})^\top (\mathbf{y} - \mathbf{f}) = (\mathbf{y} - \Phi \mathbf{w})^\top (\mathbf{y} - \Phi \mathbf{w})$$

The gradient with respect to the weights is:

$$\frac{\partial E(\mathbf{w})}{\partial \mathbf{w}} = 2 \Phi^\top (\mathbf{y} - \Phi \mathbf{w}) = 2 \Phi^\top \mathbf{y} - 2 \Phi^\top \Phi \mathbf{w}$$

The weight vector $\hat{\mathbf{w}}$ that sets the gradient to zero minimises $E(\mathbf{w})$:

$$\hat{\mathbf{w}} = (\Phi^\top \Phi)^{-1} \Phi^\top \mathbf{y}$$

A Geometrical View. This is the matrix form of the **Normal equations**.

- The vector of training targets \mathbf{y} lives in an N -dimensional vector space.
- The vector of training predictions \mathbf{f} lives in the same space, but it is constrained to being generated by the $M + 1$ columns of matrix Φ .
- The error vector \mathbf{e} is minimal if it is orthogonal to all columns of Φ :

$$\Phi^\top \mathbf{e} = 0 \iff \Phi^\top (\mathbf{y} - \Phi \mathbf{w}) = 0$$

Least squares fit for polynomials of degree 0 to 17

Have we solved the problem?

- Ok, so have we solved the problem?
- What do we think y_* is for $x_* = -0.25$? And for $x_* = 2$?
- If M is large enough, we can find a model that fits the data

Overfitting

- All the models in the figure are polynomials of degree 17 (18 weights).
- All perfectly fit the 17 training points, plus any desired y_* at $x_* = -0.25$.
- We have not solved the problem. Key missing ingredient: **assumptions!**
